Power supply and clean-energy accounting at one center

How do tasks become metered power, then enter network and hourly CFE checks?

Supply from the built grid

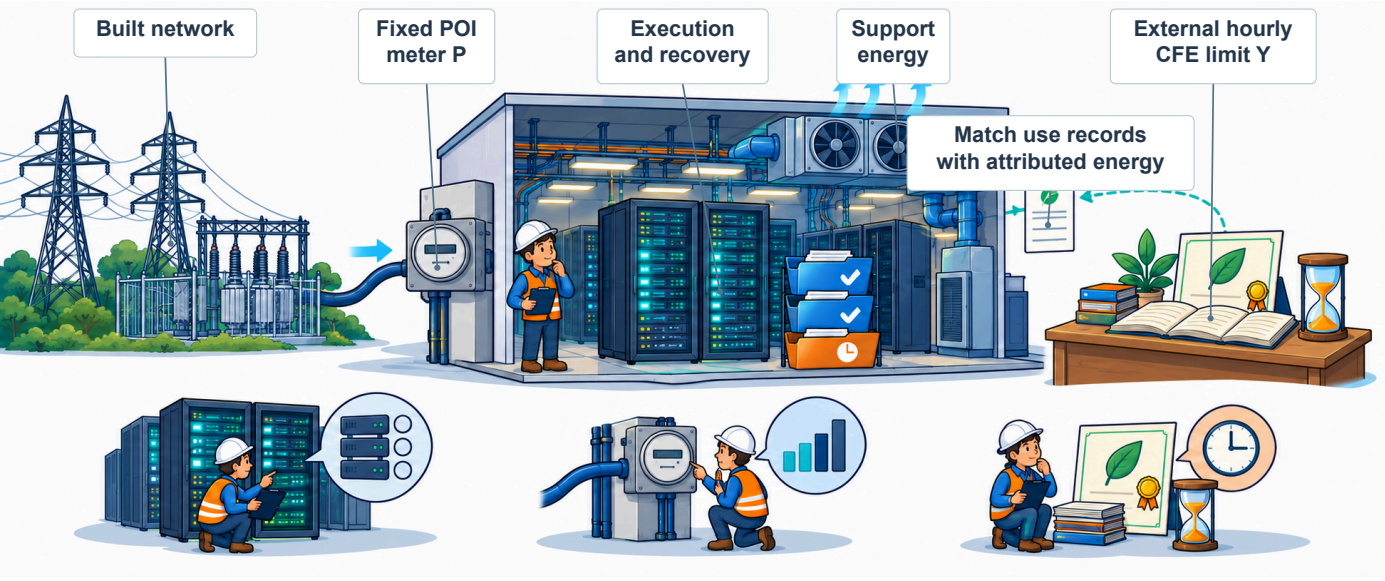

Thick blue cable: physical supply

One center, total power P

Execution, recovery, idle and support

CFE attribution for that hour

Dotted links: records and attribution

Meter records + external hourly limit Y → check CFE needed for target share α

1 Check computing resources

Execution and recovery fit within K
Deferral and recovery share $q+r \le D$
Track debt and original deadlines
Idle and support also consume power

2 Account for total power P

Map computing effort to electrical MW
P includes execution and recovery
Plus idle and support at the same meter
Energy in the interval is $P\Delta t$

3 Check network and CFE

Operation: check P on the built grid
Access: normal state checks full F+X
Contingencies: F and permitted X calls
Hourly matching: $\alpha P\Delta t \le y \le Y$
Y: externally attributable hourly energy

One center must satisfy computing-resource, network-supply and hourly clean-matching checks.
